II. Predicted probabilities

The tables presented below explore the predicted probabilities of ratification at the selected values of the independent variables. To calculate these probabilities, I used the same set of variables as in the main survival models, but in a logit model. To capture the temporal dimension of the ratification processes, I added a cubic time polynomial to the equations. While the use of this model eases the interpretation of substantive effects, it yields essentially identical results as the survival models. For the interval variables, the probabilities were calculated for values corresponding to the 10th and the 90th percentile of the given variable. For the dichotomous variables, the probabilities were calculated for values 0 and 1. In all the models, all the independent variables other than the variable of interest were kept at their mean values.

The columns 10th percentile/0 (%) and 90th percentile/1 (%) provide the information about the probability of ratification at the specified levels of the independent variables. The column Difference measures the difference between the two predicted probabilities and the column Ratio displays the ratio of the two probabilities. The probabilities and their differences generally achieve very low values, but this fully corresponds to the fact a mean probability that a state will ratify a treaty in the given year is only approximately 3%. Given this, it is meaningful to focus on the ratios of probabilities.

Table A11: Predicted probabilities (AT)

Variable	10th percentile/0 (%)	90th percentile/1 (%)	Difference	Ratio

III. Estimated survival functions

To illustrate further the substantive effects of the major explanatory variables, the below presented graphs display estimated survival functions related to a set of selected treaties (BWC, CTBT, CWC, NPT, OST, SBT). The functions were calculated on the basis of the Cox proportional hazard models from the main analysis. In the calculations underlying the graphs, the values of the explored interval variable always switched from the 10th to the 90th percentile. When the explored variable was dichotomous, they switched from 0 to 1. All the covariates other than the variable of interest were fixed at their average values.
